

AI GENERALIST ACCELERATOR · 14-DAY AI SPRINT

Bonus Office Hours Three

Office Hours Three: Enterprise Integrations, One-Key Routing, and Owning Your Model

A cleaned, detailed record of the third and final Slido question hour

Topics covered: The Automation Resource Hub · Integrating Enterprise Software · How Banks Actually Use AI · OpenRouter and GetMulti · Clones, Cheaper Models, and Data Training · The WhatsApp MCP Bridge · OpenClaw and Hermes · Closed Versus Open Source, and Renting a GPU

About This Session

The third office hour closed the week's run, Sumedha hosting on a fresh laptop, camera issue fixed, and Harshith Vaddiparthi answering for the third day straight, with the carried-over questions from days one and two taken first and Slido's thumbs-up ranking deciding the rest. Harshith opened with a delivery rather than an answer: a resource he built and vibe-coded himself, AI Automation X5 Resources, shared in chat and headed for the platform, collecting everything the three hours had raised, local Ollama installation, n8n templates ready to import, Firecrawl scraping notes, and his own client-delivery playbook for anyone running automation as an agency, how to scope, build, and hand off, updated weekly so it outlives the office hours themselves. It mattered at the close too: with thirty-seven questions still in the queue when time ran out, he committed to answering every one in writing inside that resource so nothing goes unanswered. Programme-structure questions went, as always, to support, and the hour ended with a thirty-minute break before the day-five main session on advanced MCPs.

HOW TO USE THESE NOTES

Links shared in chat and travelling with the recording: the AI Automation X5 Resources hub, the QuickBooks and NetSuite developer documentation, OpenRouter, the WhatsApp MCP repository, Ollama, and the Gemma 4 model page. Office-hour recordings and transcripts live under day three on the platform.

The week's office hours are now complete; the remaining thirty-seven Slido questions are being answered in the resource hub rather than live, so check it after the weekend.

On Integrating Enterprise Software, and How Banks Really Use AI

The first question, from a product manager in banking, financial services, and insurance wanting a prompt-based reporting tool wired to a core system, got the method that recurred all week. Pick the one enterprise tool you must connect, QuickBooks in most finance stacks, NetSuite, Xero, and open its developer documentation, a phrase not to be intimidated by since it means API documentation and software development kits; copy that link into ChatGPT, say I want to build an integration with this and here is my solution, and let the model read it. His recommendation was to do this on GPT-6 Astra in Ultra mode because it builds a knowledge graph of the documentation before helping, and his credential was a product of his own, an enterprise-grade agent built exactly this way and still in customer use. The follow-up, whether any large bank builds its core applications with AI, produced the hour's whiteboard case study: nobody rebuilds a core from scratch, and the honest reality he described from a director moving between Citi and JPMorgan Chase is migration, tens of millions of cardholder records moving from one provider's database to another as, in his telling, the Apple Card moves to Chase, no off-the-shelf tool fits, so the bank builds a hyper-specific AI tool that integrates with its existing QuickBooks, NetSuite, and SQL estate. That, he said, is how every enterprise works, chain of command, process, and a purpose-built solution over existing providers, with the aside that the banks he sees run on Claude rather than ChatGPT, presumably for security or partnership reasons, and the pitch that the cohort should hunt exactly these problems in their own networks. On Workato and similar enterprise-only automation platforms he was candid that he had not used them, that any tool offering governance will win enterprise approval, and that from where he sits n8n is the most widely used in the North American market precisely because companies self-host it on their own servers. Tally, for the learner wanting to automate a father's auto-parts billing across thousands of SKUs, got the same shape plus sympathy, his own accountant father runs Tally and SAP and dislikes AI, so the answer is find the Tally integration, define the exact problem, build the tool, and hand over an application rather than a lecture, billing and revenue-operations automation being his own most repeated client work, invoices that sit in email for sixty-day turnarounds collapsed to days by document processing.

On OpenRouter, GetMulti, and Cheaper Models

The GetMulti questions kept coming, and the answers were consistent: it is a council of LLMs, one prompt judged across several models, Claude as judge over Grok and DeepSeek, quality and web-search toggles, and no, ChatGPT or Claude subscriptions cannot be pasted into it because they are separate products, which is why yesterday's live-built Council of Experts app, now at its own subdomain, exists for anyone wanting more modularity. The learner whose redeemed coupon demanded an OpenRouter key got the concept on the whiteboard, bad arrows and all: instead of a separate API key for Claude, GPT, DeepSeek, and Kimi, OpenRouter issues one key that reaches all of them, it is what powers GetMulti underneath, and the fix is simply to sign up at OpenRouter and generate a key. The bonus-credit frustration, why give a tool that then needs paid credits, drew a fair answer, the credits are a kickstart to test the platform and get ideas, and adding your own key is the advanced step once you are ready to build. The same routing logic answered the learner who had burned all their n8n credits in two workbooks: in n8n, swap the OpenAI node for the OpenRouter node and select DeepSeek, or Qwen, the cheap and powerful Chinese models, because simple workflows do not need high cognitive load and the fraction-of-the-cost model can run for a month. Cheaper clone tools got the same discipline, Higgsfield remains the one-stop shop and now talks to Claude directly, Krea, OpenArt, and Runway are real alternatives, but the platform is not the point, the model is, so inside Higgsfield pick a cheaper model, Qwen's Wan 3 rather than Kling, Grok Image rather than Sora, and the voice-clone worry dissolved on the same principle, a voice trained in Hindi produces English or Chinese or Spanish because the model learns pitch, tone, and nuance, not language.

On Data Training, the WhatsApp Bridge, and Second Brains

Two learners asked whether business data flows into OpenAI through plugins like Outlook, and the answer reframed the fear: not leakage but training risk. Connecting Outlook does not mean ChatGPT watches your inbox, that would be a compliance violation; the plugin activates only when a prompt asks for it, summarise the latest procurement thread, and only then can the data be read and, on a consumer plan, trained on. The escape routes are the enterprise or top-tier plans, which offer the option to opt out of training, or local models for complete privacy. The WhatsApp question got a live installation. His own ChatGPT, addressed as Jarvis, was asked to look into WhatsApp and did, through a WhatsApp MCP server from a public GitHub repository, and the steps for the learner were three: copy the repository link, open a new chat in ChatGPT or Claude or any harness, and say install this and show me how. The model walks the whole setup, your computer becomes a bridge between WhatsApp and the LLM, data stored locally, paired through Linked Devices and a QR code like any linked device, with the warning not to scan his on-screen code unless you want him reading your messages, and the difference from WhatsApp Desktop stated plainly, the desktop app is the app, the MCP lets you say summarise this group and tell me what is going on. OpenClaw, asked about as a beginner-versus-advanced choice, got both a demonstration and a demystification: it is an architecture, one single brain living on his own server, given memory and every plugin and MCP he owns, Outlook, his newsletter, all of it, building on itself daily as a second brain, given a voice so that, asked live, it greeted the room; underneath the Iron Man theatre it is all integrations, and Hermes is the alternative he also runs. The beginner-versus-advanced framing itself he retired: the tools now adapt to you, if you do not understand something you say calm it down, Codex is just the ChatGPT app in work mode, Claude's chat and work modes are merging, and everything is becoming one super app.

On Plugins, Worksheets, Llama, and Owning Your Model

The mechanics questions were quick. Connecting a plugin in ChatGPT is the plugins button, the plus icon, and connect. Getting your own in-house application into that list means building your own MCP server and approaching OpenAI's partner team for vetting, but the absence of a listing should not stop anyone, since most connectors started life as unlisted custom builds. The why-Gamma complaint about the day-one worksheet got a principle: worksheets are not about the tools, they are about the approach, the plugin lesson survives whether you output through Gamma, Canva, PowerPoint, or any Microsoft tool, and Gamma simply happens to be widely used and easy. Using the course transcripts and Q&A; as a private RAG knowledge base is not just permitted but encouraged, in NotebookLM or a ChatGPT project, with formal permission questions routed to the Outskill team. Llama versus Ollama needed separating: Llama is Meta's model family, Ollama is an unrelated application best thought of as an app store for open-source models, where Gemma 4, Google's open-source line as distinct from its proprietary Gemini 4, installs in one command and runs with no internet and no subscription. And the privacy question that closed the hour became a map. On one side the closed-source models, Claude, ChatGPT, Gemini, paid by subscription or API usage, where borrowing intelligence from a model like GPT-6 Astra is a straight trade against privacy; on the other the open-source models, DeepSeek, Qwen, Moonshot's Kimi, GLM, which add a third option, download the whole model and use it free. The caveat is compute, a frontier open model needs a GPU setup around twenty thousand dollars, or a purpose-built box like the NVIDIA DGX Spark he has on order at roughly six thousand, or, the practical route, renting a GPU server for about twenty dollars a month and running Kimi K3 or GLM on it, paying for rent instead of API credits, with every computation on a server that is yours and a model that is completely yours.

THE MENTAL MODEL

Enterprise integration is a documentation link handed to a strong model; banks migrate and integrate rather than rebuild. One OpenRouter key reaches every model, and cheap open models handle simple workflows. Plugins activate only when prompted, so the risk is training, not surveillance, answered by enterprise plans or local models. And the ladder ends with owning the model outright, rented GPU or DGX box, computation on your own server.

Key Takeaways

Stripped to its essentials, the hour made the following points.

- **Integrate by documentation.** QuickBooks, NetSuite, Xero, Tally: find the developer docs, hand the link to a strong model, describe your solution, and build the tool that plugs into the existing stack, which is exactly how enterprises and banks do it.
- **Banks migrate, they don't rebuild.** No core system is being rewritten with AI; the real work is purpose-built tools over existing providers, the tens of millions of records moving between card providers being the live example, and those problems are the ones to pitch.

- **One key, every model.** OpenRouter replaces a key per provider with a single key across Claude, GPT, DeepSeek, and Kimi, powers GetMulti underneath, and in n8n the OpenRouter node with DeepSeek or Qwen stretches credits from days to a month.
- **The model is the point, not the platform.** Inside Higgsfield choose cheaper models like Wan 3 or Grok Image, alternatives like Runway exist, and a voice clone trained in Hindi speaks any language because it learns tone, not words.
- **Plugins wake on prompt.** Outlook is read only when you ask, so the risk is training on a consumer plan, avoided by enterprise plans or local models; a WhatsApp MCP bridge installs from a GitHub link with `install this` and `show me how`.
- **Second brains are integrations.** OpenClaw or Hermes on your own server with memory, plugins, and a voice is one brain over everything you connect, and beginner-versus-advanced no longer applies because the tools adapt to you.
- **Own your model when privacy matters.** Closed models trade privacy for intelligence; open models like DeepSeek, Qwen, Kimi K3, and GLM download free and run on a rented GPU for about twenty dollars a month or a DGX box, computation entirely yours.
- **Nothing goes unanswered.** The AI Automation X5 resource hub carries the client-delivery playbook, Ollama and n8n templates, and written answers to every one of the thirty-seven questions the hour could not reach.

End of Office Hours Three notes. Office hours resume after the weekend sessions.
